Flow of Execution

2

- Execution always begins at the first statement in the function **main**
- Other functions are executed **only when they are called**
- Function prototypes appear **before any function definition**
 - The compiler translates these **first**
- The compiler can then correctly translate a function call

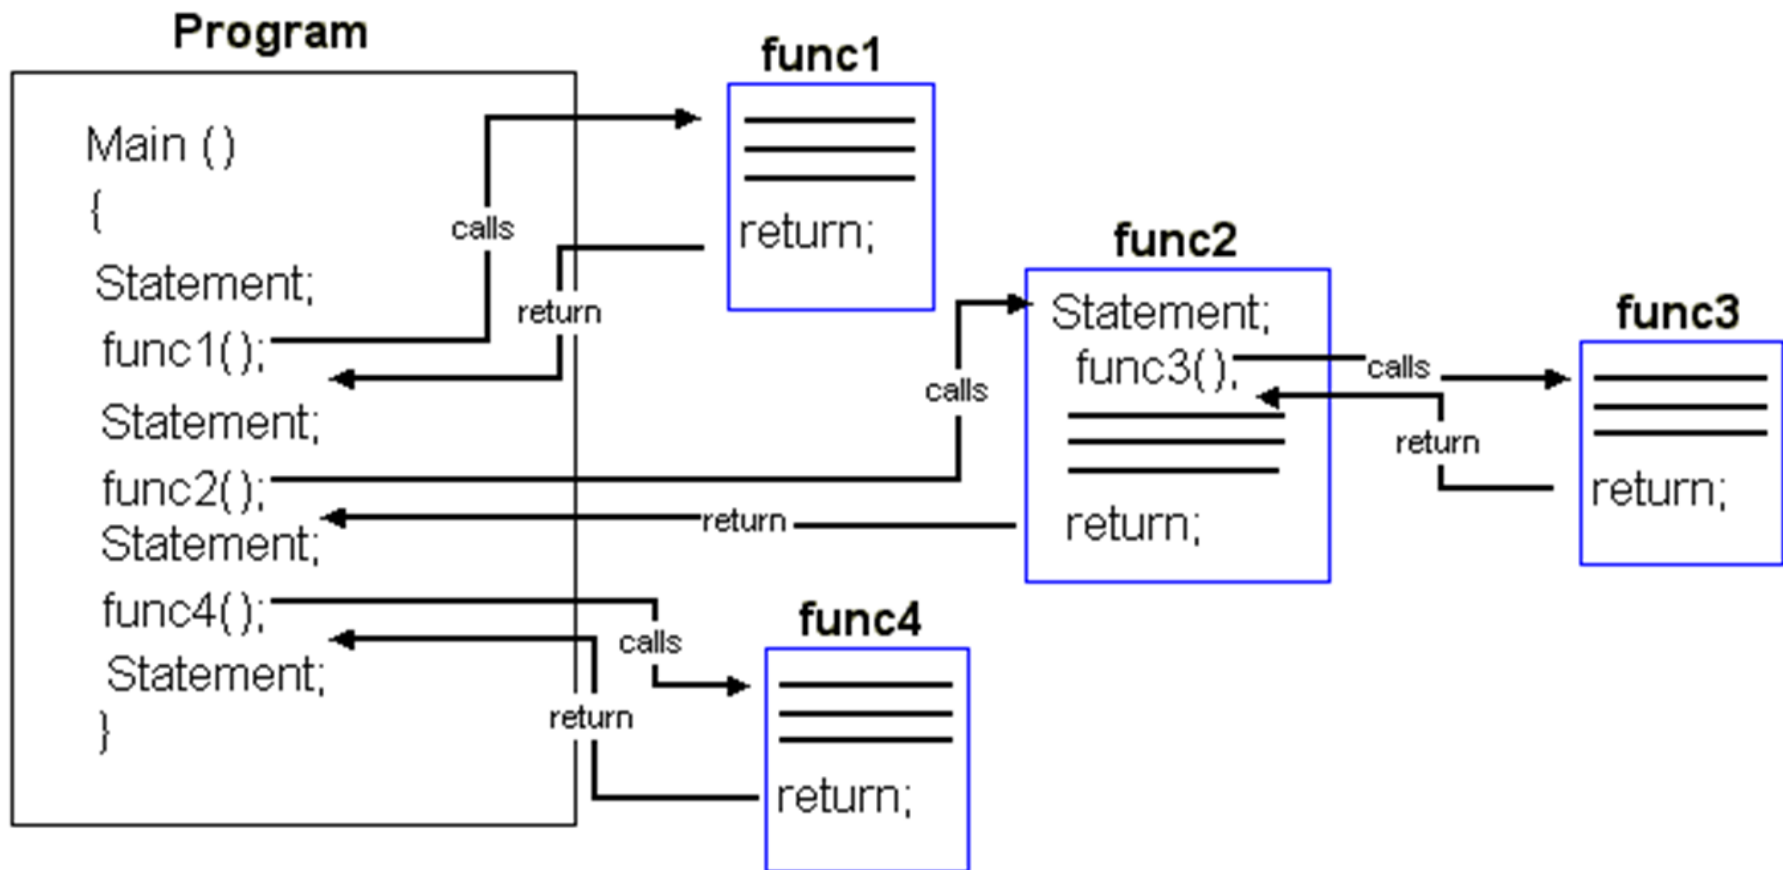

Flow of Execution (cont'd.)

3

- A function call results in **transfer of control** to the first statement in the body of the called function
- After the last statement of a function is executed, **control is passed** back to the point immediately following the function call
- A value-returning function returns a value
 - After executing the function the returned value replaces the function call statement

Conti...

4

void Functions

5

- **void** functions and value-returning functions have similar structures
 - Both have a heading part and a statement part
- User-defined void functions can be placed either before or after the function **main**
- If user-defined void functions are placed after the function **main**
 - The function prototype must be placed before the function **main**

void Functions (cont'd.)

6

- A void function does not have a return type
 - **return** statement without any value is typically used to exit the function **early**.
 - **It can be used** in void **for early termination**
- Formal parameters are **optional**
- A call to a void function is a stand-alone statement

void Functions (cont'd.)

7

- Function definition syntax:

```
void functionName(formal parameter list)
{
    statements
}
```

- Formal parameter list syntax:

```
dataType& variable, dataType& variable, ...
```

Void Functions (cont'd.)

8

- Function call syntax:

```
functionName(actual parameter list);
```

- Actual parameter list syntax:

```
expression or variable, expression or variable, ...
```

void Functions (cont'd.)

9

- **Value parameter:** A formal parameter that receives a copy of the content of corresponding actual parameter
- **Reference parameter:** A formal parameter that receives the location (memory address) of the corresponding actual parameter

void Functions (cont'd.)

10

EXAMPLE 7-1

```
void funexp(int a, double b, char c, int x)
{
    .
    .
    .
}
```

The function `funexp` has four parameters.

void Functions (cont'd.)

11

EXAMPLE 7-2

```
void expfun(int one, int& two, char three, double& four)
{
    .
    .
    .
}
```

The function `expfun` has four parameters: (1) `one`, a value parameter of type `int`; (2) `two`, a reference parameter of type `int`; (3) `three`, a value parameter of type `char`; and (4) `four`, a reference parameter of type `double`.

value Parameters

12

- If a formal parameter is a **value parameter**
 - The value of the corresponding **actual parameter** is **copied** into it
- The value parameter has its own copy of the data
- During program execution
 - The value parameter **manipulates the data** stored in its own **memory space**

Example

13

```
void funcValueParam(int num);

int main()
{
    int number = 6; //Line 1

    cout << "Line 2: Before calling the function "
          << "funcValueParam, number = " << number
          << endl; //Line 2

    funcValueParam(number); //Line 3

    cout << "Line 4: After calling the function "
          << "funcValueParam, number = " << number
          << endl; //Line 4

    return 0;
}

void funcValueParam(int num)
{
    cout << "Line 5: In the function funcValueParam, "
          << "before changing, num = " << num
          << endl; //Line 5

    num = 15; //Line 6

    cout << "Line 7: In the function funcValueParam, "
          << "after changing, num = " << num
          << endl; //Line 7
}
```

Reference Variables as Parameters

14

- If a formal parameter is a **reference parameter**
 - It receives the **memory address of** the corresponding **actual parameter**
- A reference parameter **stores the address** of the corresponding actual parameter
- During program execution to manipulate data
 - The **address** stored in the reference parameter directs it to the **memory space** of the corresponding **actual parameter**

Reference Variables Benefits

15

- **Reference parameters can:**
 - Pass one or more values from a function
 - Change the value of the actual parameter
- **Reference parameters are useful in three situations:**
 - Returning more than one value
 - Changing the actual parameter
 - When passing the address would save memory space and time

Example 7-5: Calculate Grade

```
//This program reads a course score and prints the
//associated course grade

#include<iostream>
using namespace std;
void getScore(int& score);
void printGrade(int cScore);

int main()
{
    int courseScore;
    cout << "Line 1: Based on the course score, \n"
         << "\tthis program computes the "
         << "course grade." << endl;           //Line 1

    getScore(courseScore);                     //Line 2
    printGrade(courseScore);                   //Line 3

    return 0;
}
```

Example 7-5: Calculate Grade

17

```
void getScore(int& score)
{
    cout << "Line 4: Enter course score: ";    //Line 4
    cin >> score;                               //Line 5
    cout << endl << "Line 6: Course score is "
         << score << endl;                     //Line 6
}

void printGrade(int cScore)
{
    cout << "Line 7: Your grade for the course is ";    //Line 7
    if (cScore >= 90)                                     //Line 8
        cout << "A." << endl;
    else if (cScore >= 80)
        cout << "B." << endl;
    else if (cScore >= 70)
        cout << "C." << endl;
    else if (cScore >= 60)
        cout << "D." << endl;
    else
        cout << "F." << endl;
}
```

Example 7-5: Calculate Grade (cont'd.)

18

FIGURE 7-1 Variable `courseScore` and the parameter `score`

FIGURE 7-2 Variable `courseScore` and the parameter `score` after the statement in Line 5 executes

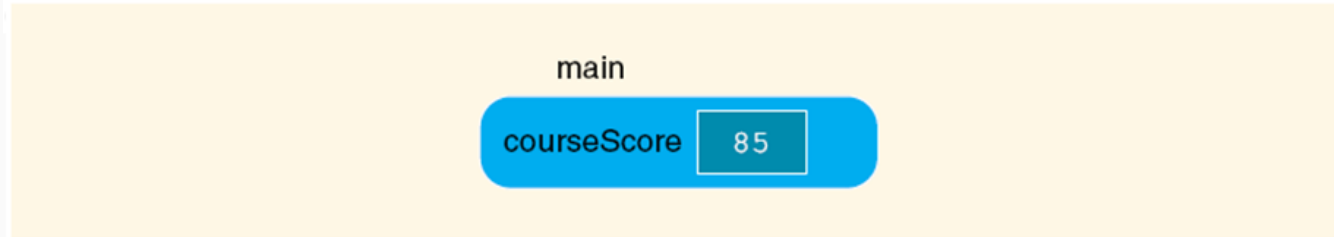

FIGURE 7-3 Variable `courseScore` after the statement in Line 6 is executed and control goes back to `main`

FIGURE 7-4 Variable `courseScore` and the parameter `cScore`

Value and Reference Parameters and Memory Allocation

- When a function is called
 - Memory for its formal parameters and variables declared in the **body** of the function (**called local variables**) is allocated in the function data area
- In the case of a **value parameter**
 - The value of the actual parameter is copied into the memory cell of its corresponding formal parameter

Value and Reference Parameters and Memory Allocation (cont'd.)

- In the case of a **reference parameter**
 - The address of the actual parameter passes to the formal parameter
- Content of formal parameter is an **address**
- During execution, changes made by the formal parameter **permanently** change the value of the actual parameter

Value and Reference Parameters and Memory Allocation (cont'd.)

// This following program shows how reference and value parameter work
//Example 7-6: Reference and Value parameter

```
#include <iostream>
using namespace std;
void funOne(int a, int& b, char c);
void funTwo(int& x, int y, char& w);
int main(){
    int num1 = 10, num2 = 15;
    char ch = 'A';
    cout << "Line 4: Inside main: num1 = " << num1
         << ", num2 = " << num2 << ", ch = "
         << ch << endl;           //Line 4
    funOne(num1, num2, ch);       //Line 5
    cout << "Line 6: Inside main After funOne: num1 = " << num1
         << ", num2 = " << num2 << ", ch = "
         << ch << endl;           //Line 6
    funTwo(num2, 25, ch);         //Line 7
    cout << "Line 8: Inside main After funOne: num1 = " << num1
         << ", num2 = " << num2 << ", ch = "
         << ch << endl;           //Line 8
    return 0;
}
```

Value and Reference Parameters and Memory Allocation (cont'd.)

```
void funOne(int a, int& b, char c)
{
    int one;
    one = a;           //Line 9
    a++;               //Line 10
    b = b * 2;         //Line 11
    c = 'B';           //Line 12

    cout << "Line 13: Inside funOne: a = " << a
          << ", b = " << b << ", c = " << c
          << ", and one = " << one << endl;    //Line 13
}

void funTwo(int& x, int y, char& w)
{
    x++;               //Line 14
    y = y * 2;         //Line 15
    w = 'G';           //Line 16

    cout << "Line 17: Inside funTwo: x = " << x
          << ", y = " << y << ", and w = " << w
          << endl;      //Line 17
}
```

Value and Reference Parameters and Memory Allocation (cont'd.)

Sample Run:

```
Line 4: Inside main: num1 = 10, num2 = 15, and ch = A
Line 13: Inside funOne: a = 11, b = 30, v = B, and one = 10
Line 6: After funOne: num1 = 10, num2 = 30, and ch = A
Line 17: Inside funTwo: x = 31, y = 50, and w = G
Line 8: After funTwo: num1 = 10, num2 = 31, and ch = G
```

```
//Example 7-7: Reference and value parameters.
```

```
//Program: Makes you think.
```

```
#include <iostream>
```

```
using namespace std;
```

```
void addFirst(int& first, int& second);
```

```
void doubleFirst(int one, int two);
```

```
void squareFirst(int& ref, int val);
```

```
int main()
```

```
{
```

```
    int num = 5;
```

```
    cout << "Line 1: Inside main: num = " << num  
         << endl;
```

```
//Line 1
```

```
    addFirst(num, num);
```

```
//Line 2
```

```
    cout << "Line 3: Inside main after addFirst:"  
         << " num = " << num << endl;
```

```
//Line 3
```

```
    doubleFirst(num, num);
```

```
//Line 4
```

```
    cout << "Line 5: Inside main after "  
         << "doubleFirst: num = " << num << endl;
```

```
//Line 5
```

```
    squareFirst(num, num);
```

```
//Line 6
```

```
    cout << "Line 7: Inside main after "  
         << "squareFirst: num = " << num << endl;
```

```
//Line 7
```

```
    return 0;
```

```
}
```

```
void addFirst(int& first, int& second)
{
    cout << "Line 8: Inside addFirst:  first = "
          << first << ", second = " << second << endl; //Line 8

    first = first + 2;                                     //Line 9

    cout << "Line 10: Inside addFirst:  first = "
          << first << ", second = " << second << endl; //Line 10

    second = second * 2;                                   //Line 11

    cout << "Line 12: Inside addFirst:  first = "
          << first << ", second = " << second << endl; //Line 12
}

void doubleFirst(int one, int two)
{
    cout << "Line 13: Inside doubleFirst:  one = "
          << one << ", two = " << two << endl;           //Line 13

    one = one * 2;                                         //Line 14

    cout << "Line 15: Inside doubleFirst:  one = "
          << one << ", two = " << two << endl;           //Line 15

    two = two + 2;                                         //Line 16

    cout << "Line 17: Inside doubleFirst:  one = "
          << one << ", two = " << two << endl;           //Line 17
}
```

```

void squareFirst(int& ref, int val)
{
    cout << "Line 18: Inside squareFirst: ref = "
          << ref << ", val = " << val << endl;           //Line 18

    ref = ref * ref;                                       //Line 19

    cout << "Line 20: Inside squareFirst: ref = "
          << ref << ", val = " << val << endl;           //Line 20

    val = val + 2;                                         //Line 21

    cout << "Line 22: Inside squareFirst: ref = "
          << ref << ", val = " << val << endl;           //Line 22
}

```

Sample Run:

```

Line 1: Inside main:  num = 5
Line 8: Inside addFirst:  first = 5, second = 5
Line 10: Inside addFirst:  first = 7, second = 7
Line 12: Inside addFirst:  first = 14, second = 14
Line 3: Inside main after addFirst:  num = 14
Line 13: Inside doubleFirst:  one = 14, two = 14
Line 15: Inside doubleFirst:  one = 28, two = 14
Line 17: Inside doubleFirst:  one = 28, two = 16
Line 5: Inside main after doubleFirst:  num = 14
Line 18: Inside squareFirst: ref = 14, val = 14
Line 20: Inside squareFirst: ref = 196, val = 14
Line 22: Inside squareFirst: ref = 196, val = 16
Line 7: Inside main after squareFirst:  num = 196

```

FIGURE 7-19 Parameters of the function `squareFirst`

Reference Parameters and Value-Returning Functions

- ▶ You can also use reference parameters in a value-returning function
 - ▶ Not recommended
- ▶ By definition, a value-returning function returns a single value
 - ▶ This value is returned via the return statement
- ▶ If a function needs to return **more than one value**, you should change it to a **void function** and use the appropriate reference parameters to return the values

Using Functions in a Menu-Driven Program

Functions can be used:

- To implement user choices from menu
- To implement general-purpose tasks
 - Higher-level functions can call general-purpose functions
 - This minimizes the total number of functions and speeds program development time
